Solid State Pressure Sensor

CCD Series – Model 54D

FEATURES

- DIP or SMD Package
- Calibrated Span and Offset
- Multi-order Temperature compensation
- OWI, I²C or SPI Interface
- 3V or 5V Supply
- Customized Configuration upon request

DESCRIPTION

The Series CCD Model 54D is a smart pressure transducer with digital output via 1-wire serial, I²C or SPI interface. Digital compensation of sensor offset, sensitivity, temperature drift and nonlinearity is accomplished in factory via an internal DSP running a correction algorithm with calibration coefficients stored in on-chip EEPROM.

A variety of characteristic configuration, including accuracy, sampling rate, temperature compensated range are available to provide simple and ready-to-use solution for a wide rage of application. It can be operated in supply voltage of 2.7 to 5.5 V, and can be extended to 30V with an external JFET.

The Series CCD is available for pressure range from 0.15 psi to 150 psi. Special configuration as low as 2.5 mbar is also applicable. Please contact factory for detail.
Ordering Information
Series CCD 54 Digital

54D L - XXX G - X 0 X X

Option
0: No special request

Sampling Rate
0 = 1 kHz
1 = 200 Hz
2 = 40 Hz
3 = 8 Hz

Series

Type of Pressure
G: Gage (Port B only)
H: Gage (Dual Port)
A: Absolute (Port A only)
D: Differential
I: Negative Gage (Port B only)

Supply Voltage
Blank = 4.75 to 5.25 V
L = 2.75 to 3.33 V

Pressure range
Medium Pressure
003 = 0 ~ 3 psi
005 = 0 ~ 5 psi
007 = 0 ~ 7 psi
015 = 0 ~ 15 psi
030 = 0 ~ 30 psi
050 = 0 ~ 50 psi
100 = 0 ~ 100 psi
150 = 0 ~ 150 psi

Low Pressure
L15 = 0 ~ 0.15 psi
L30 = 0 ~ 0.3 psi
L50 = 0 ~ 0.5 psi
L70 = 0 ~ 0.7 psi

Ultra-low Pressure
L03 = 0 ~ 2.5 mbar
L07 = 0 ~ 5 mbar

Type of Output
0 = 1-wire P
1 = 1-wire P+T
2 = 0.5 to 4.5 V
3 = 0.2 to 4.8 V
4 = N/A
5 = 0 to 1 V
6 = 0.2 to 4.7 V
7 = N/A
8 = I²C
9 = SPI
S = Special

Leading Direction
1 = Leads opposite side as Port A
2 = Leads same side as Port A
3 = J-bend Leads same side as Port A

Notes:
Custom ranges and units are available upon request.
Please contact factory.

NOTES:
1. Specifying differential pressure means a ± pressure range.
2. Differential pressure can be specified to a maximum of +/- 150 psi.
3. Custom output, pressure range and temperature compensated range are available.
4. Negative gage normally has offset (0.5V) at 0 psi and full scale output (4.5V). Reverse is also applicable.
5. Accuracy may vary on pressure range
6. Minimum absolute pressure that can be specified is 15 psia
7. Medium is available for clean air. For other medium please contact factory.
**Characteristics**

Unless otherwise specified, all parameters are measured at 3/5V, 25 °C and 60% RH

**NOTES:**
1. Supply 3V or 5V must be ordered separately.
2. Smaller range and other units are also available for ordering.
3. Accuracy includes NOL, hysteresis, TCS and TCO over 0/50°C, BFSIL definition.
6. Wetted material: PA, RTV, Epoxy, ceramic, Au, nickel and silicon.
7. Output is ratiometric to supply voltage.
8. Output load resistance to Vss or Vdd: 2.5K (min), 10K (typ).

**Dimension**

- **Leading ID**
  - NOTE: Port B is used for positive differential.
  - Port A is used for absolute.
  - Port B is used for gage.
  - All dimensions are mm.
  - Tube Size: Tygon tube, 4 (o.d.) 2.5 (i.d.) mm.

- **Pin # Description**
  - 1: N.C.
  - 2: VSS
  - 3: OUT
  - 4: VDD
  - 5~8: N.C.

**NOTES:**
- N.C. pins must be left floating.
- A 0.1uf capacitor must be connected between Vss and Vdd.
- Package: 12 pcs/tube.
### Characteristics

Communication Interface

Manchester codes by a transition at the cell boundary are used to represent the binary values of pressure and temperature.

Bit Encoding

- **Start Bit**: 50% duty cycle used to set up strobe time.
- **Logic 1**: 75% duty cycle.
- **Logic 0**: 25% duty cycle.

Read Operation

There are two modes (DPT digital pressure output with temperature, and DTO digital pressure out only) available for the output of transducer.

For **DPO** mode, the transducer first transmits the high byte of pressure data followed by the low byte. The pressure data is 14-bits in resolution, so the upper two bits of the high byte are always zero padded. There is a half stop bit interval between bytes in a packet. That means for the time of half a bit width, the signal level is in high level.

For **DPT** mode, the pressure and temperature will be transmitted as 3 data packets.
Timing

The baud rate (transmission frequency) of the Manchester coded bit stream is determined during factory calibration and depends on the update rate and thus response time that the customer specifies for the transducer. If no response time is specified by the customer the default response time of 5ms (200Hz) will be selected.

There are a total of 4 different update rates listed below. Using the two faster update rates will result in the baud rate being 32kHz and the two slower update rates will result in the baud rate being set to 8kHz.

Hints for Writing Firmware:

The Baud rates (8kHz and 32kHz respectively) will vary +/- 10% with the supply voltage and across temperature. It is strongly recommended that any firmware used the read the digital pressure and temperature readings first use the start bit which is 50% high and 50% low to determine the exact frequency before decoding the digital output.

The idle time is the time in between data packets where no transmission occurs (the output is always high when idle).

Suggested Algorithm:

Connect the output of the sensor to a pin of a microcontroller capable of causing an interrupt on a falling edge. When the falling edge is detected this causes a branch into an ISR which is a counting loop incrementing until a rising edge is detected in the output. Now based on the number of counts the frequency can be determined.

Now that the frequency is know the ISR can simply wait for the appropriate time before sampling the other bits.
How to Interpret the Pressure Value

The CCD series pressure sensors have been calibrated to a straight line transfer function. The pressure value can be easily obtained by inserting the output into the transfer function. The process is explained below.

The pressure value is read out as a 14 bit word. The word corresponds to 0x0000 to 0x3FFF in Hex or 0 to 16383 in Decimal.

The first step is to convert the Hex value to Decimal. The calculator supplied with Microsoft Windows will easily do this.

The next step is to port the decimal value into the straight line function shown in the chart below.

The following example is for a -5 to +5 psi transfer function:

The output word is 0x1ABC.

The output word is translated into decimal which is 6844

The decimal word is then inserted into the equation which gives:

$6844 = 1310.6x + 8191.5$ where $x$ is the pressure in psi

We then compute $x = -1.028$ psi

*Note: The transfer function varies for each pressure range. Make sure you use the correct function. If in doubt please consult the factory.*
Obtaining the transfer function:

The transfer function is a straight line equation in the standard form $y=mx+c$, where $y$ and $x$ are $x,y$ coordinates, $m$ is the gradient and $c$ is the $y$-axis intercept.

To compute your straight line transfer function you will simply need the 2 sets of $x,y$ coordinates. These will be supplied to you with outputs of 10%FS and 90% FS by default (custom outputs are available on request).

Example:

Pressure = 0 psi, Output 10% FS
Pressure = 100 psi, Output 90% FS

First we note that the output is 14 bits ie. 0x0000 to 0x3FFF. In decimal this becomes 0 to 16383.

10% FS is 1638
90% FS is 14745

First we find the gradient $m$, of our straight line.

$$m = \frac{(y_2-y_1)}{(x_2-x_1)}$$
$$= \frac{(14745-1638)}{(100\text{psi}-0\text{psi})}$$
$$= 131.07$$

Now we substitute this in and we get:

$$y = 131.07x + c$$

We substitute $y=1638$ when $x=0$ and we get

$$c = 1638$$

Which leaves us with our transfer function:

$$y = 131.07x + 1638$$ where $y$ is the output in Hex and $x$ is the corresponding pressure

Note that the pressure $x$, can be specified in any units bar, psi...etc in which case the transfer function will only be valid for that particular pressure unit.
AN05 (Preliminary)

Digital Output Description for $I^2C$ Pressure Sensors (I Series)

This Application Note applies to the following pressure sensors:
CCD Series 53I and 54I
MAP Series 36I
SLP Series 33I and 35I
SPD Series 34I

Abstract:

This application note describes in detail the digital output format of Sensormate’s I Series digital pressure sensors with $I^2C$ output.

Design considerations as well as hints for writing interface firmware with an MCU are given.

After reading this application note the user should be able to:
- Be able to issue commands to initiate a pressure measurement and read out the result
- Calculate the transfer function for his/her respective sensor

Foreword

The I Series pressure sensors from Sensormate Enterprise represent the next generation in digital pressure sensing. Designed to be Microcontroller friendly and optimized for battery powered operation. Among the key features:
- $I^2C$ interface with different address options
- Sleep mode with 2$\mu$A standby current
- Peak operating current of 2mA
- Low voltage operation from 2.7V to 5.5V and as low as 2.4V with de-rated accuracy.
## I²C Communication Parameters

**Notes**
1) Relative to SCL Edge
2) Combined low and high widths must equal or exceed minimum SCL period
3) All Timing is subject to a ±10% variation

**Sensor Operation**

The operation of Sensormate’s I Series pressure sensors are detailed by the ASM chart on the following page.

Upon power on the sensor performs various reset and initialization functions. This will take 6 ms before entering into ‘Sleep Mode’. The sensor remains in this mode whenever not in use to conserve power.

To initiate a pressure measurement, the I²C master issues a Read_MR command. This prompts the sensor to initiate a pressure measurement. The process takes 25 ms to complete the measurement after which it re-enters Sleep Mode.

After the result is ready it can be read out using Read_DF2 or Read_DF3 commands depending on what data is required to be read.

After the read command, the sensor returns to the Sleep Mode and waits for the next command to initiate pressure measurement.

i²C Packet Reading

Note: We do not guarantee the accuracy of the Temperature output but instead provide it as an added feature at no extra cost.
Working Mode Description

1. Power On

2. Reset Functions

3. Power Down (Wait for Command)

4. Command Received

   - If yes, I²C Read MR
   - If no, go to next step

5. I²C Read DF2 or I²C Read DF3/4

6. Perform Measurement

7. Power Down (Wait for Command)

8. Command Received

   - If yes, Fetch Data
   - If no, go to previous step

9. 6.5 ms

10. 25 ms
How to Interpret the Pressure/Temperature Value

All digital pressure sensors have been calibrated to a straight line transfer function. Temperature and non-linearity compensation are already included and are transparent to the user. The pressure value can be easily obtained by inserting the output into the transfer function. The process is explained below.

The pressure value is read out as a 14 bit word. The word corresponds to 0x0000 to 0x3FFF in Hex or 0 to 16383 in Decimal.

The first step is to convert the Hex value to Decimal. The calculator supplied with Microsoft Windows will easily do this.

The next step is to port the decimal value into the straight line function shown in the chart below.

The following example is for a -5 to +5 psi transfer function:

The output word is 0x1ABC.
The output word is translated into decimal which is 6844
The decimal word is then inserted into the equation which gives:

\[ 6844 = 1310.6x + 8191.5 \]

where \( x \) is the pressure in psi

We then compute \( x = -1.028 \) psi

*Note: The transfer function varies for each pressure range. Make sure you use the correct function. The transfer functions for standard ranges are found on the next page
**Transfer Function**

To obtain the transfer function we start with the two parameters found in the sensor datasheet shown again below for convenience.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Min</th>
<th>Typ</th>
<th>Max</th>
<th>Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zero Output</td>
<td>0666</td>
<td></td>
<td></td>
<td>Hex</td>
</tr>
<tr>
<td>Full Scale Output</td>
<td>3996</td>
<td></td>
<td></td>
<td>Hex</td>
</tr>
</tbody>
</table>

Zero output = 0x0666 and Full Scale output = 0x3996.

The total output resolution is 14 bits or 0x3FFF.

We convert these into decimal for convenience:
Zero output = 1638, Full Scale output = 14742 and Total output resolution = 16383

Note that 1638 is 10% of total resolution and 14742 is 90% of total resolution so only 80% of the total 14 bit resolution is used to represent the required FS.

Now we correlate the outputs to the pressure range (see ordering guide in datasheet on how to specify pressure range). The example below refers to the output function on the previous page.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Corresponding Pressure</th>
<th>Hex</th>
<th>Decimal</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zero Output</td>
<td>-5 psi</td>
<td>0x0666</td>
<td>1638</td>
</tr>
<tr>
<td>Full Scale Output</td>
<td>+ 5 psi</td>
<td>0x3996</td>
<td>14742</td>
</tr>
</tbody>
</table>

So taking the coordinates (-5 psi, 1638 counts) and (+5 psi, 14742 counts) we can calculate the corresponding straight line transfer function by calculating the gradient and Y-axis intercept.

In this case it is \( Y = 1310.6X + 8191.5 \) where Y=Digital output in Decimal and X=pressure in psi

**Temperature Transfer Function:**

<table>
<thead>
<tr>
<th>Temperature Range</th>
<th>Transfer Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>-50 to 150 °C</td>
<td>( y = 1.275x + 63.75 ) (8 bit (MSB) version)</td>
</tr>
<tr>
<td>-50 to 150 °C</td>
<td>( y = 10.24x + 512 ) (11 bit version)</td>
</tr>
</tbody>
</table>

Note: The temperature transfer function is the same regardless of the pressure range chosen. The temperature output is not intended for high accuracy measurements but is instead an additional function provided at no extra cost.
**Effective Resolution**

While the resolution is stated as 14 bits in the datasheet it is impossible to attain this resolution in practice.

14 bits is merely the resolution of the internal Analog to Digital converter (ADC) of the ASIC used to achieve the digital compensation and output.

In practice its resolution will be lower than 14 bits with quantization noise and amplification errors that result in a non-perfect match of the input range of the ADC to the sensor being compensated.

Therefore the guaranteed resolution of Sensormate sensors is 0.05% FS or 11 bits.

In most cases the software designed to read the pressure word should (where possible) allow for an averaging of 2-8 readings. The exact resolution versus sampling speed should be determined by the customer as it is very much dependent on the application.
